A soil is said to be elastic when it suffers a reduction in volume (or is changed in shape and bulk) while the load is applied, but recovers its initial volume immediately the load is removed. The most important characteristic of the elastic behaviour of soil is that no matter how many repetitions of load are applied to it, provided that the stresses set up in the soil do not exceed the "yield stresses" the soil does not become permanently deformed.

Poulos H.G., Davis E.H. Elastic solutions for soil and rock mechanics. New York: John Wiley & Sons, Inc., 1974. — 411 p. The authors have attempted to assemble as comprehensive a collection as possible of graphs, tables and explicit solution of problems in elasticity relevant to soil and rock mechanics. Many of these solutions are well known and widely used in geotechnical practice, and are available in standard references.

This paper focuses on procedures for estimating modulus values for soils that are useable with simple elastic solutions and linear finite element analyses for stresses and deformations. Relationships among Young's modulus, shear modulus, constrained modulus, and bulk modulus are defined so that correlations for any of these various measures of soil stiffness can be adapted to the purpose at hand.

Balmer (1958) found that the elastic modulus of soil-cement mixture increases with cement dosage and varies from 100,000 psi (689 MPa) to 2,000,000 psi (13.79 GPa) for granular soil-cement mixture and from 260,000 (1.79 GPa) to 760,000 psi (5.24 GPa) for fine-grained soil-cement mixture.

Fig. 4 shows approximate solutions for the lining when there is a void. The tunnel is assumed to be built in rock and the range of the void is 60°. These solutions satisfy the boundary condition at equidistantly selected N discrete points at the ground-lining interface $r = R$. The vertical axis $f(r, \theta)$, $u(r, \theta)$, and $\sigma_{\theta}(r, \theta)$ are normalized by each solution with no void at $r = R$.

Elastic modulus of soil is the parameter and the measure of stiffness of soil. Sometimes, it is also termed as Young's modulus. It is found by dividing the stress by strain taken inside the range of clay soil's elastic behavior. The undrained elastic modulus is denoted by E_u and will be acquired from the Undrained Triaxial test data, while the drained modulus E_d is obtained from the drained test condition.
